

# Week #3

## Basic Query Formulation

SQL :- Structured query language.  
SQL has 3 types of Statements :-  
Definition  
Control  
Manipulation

SQL performance incurs reduced portability across DBMS's & higher switching costs.  
SQL is a broad language with weak conformance.  
For single table problems, you must know the columns of a table & data types.

Join Operators :-  
Used to combine tables in Databases.  
→ Equi-Join (when join operator involves "=")

# University Database :-

Course	
P * COURSENO	CHAR(6 BYTE)
* CRSDCS	VAR(CHAR(30 BYTE))
CRSUNITS	NUMBER(*10)

FACULTY	
P * FACNO	
* FACFIRSTNAME	
* FACLASTNAME	
* FACCCITY	
* FACSTATE	
* FACZIPCODE	
FACRANK	
FACHIREDATE	
FAC SALARY	
FAC SUPERVISOR	
FAC DEPT	

OFFERING	
P * OFFERNO	NUMBER(*10)
* COURSENO	CHAR(6 BYTE)
* OFFTERM	CHAR(6 BYTE)
* OFFYEAR	NUMBER(*10)
OFFLOCATION	VAR(CHAR(30 BYTE))
OFFTIME	VAR(CHAR(20 BYTE))
FACNO	CHAR(11 BYTE)
OFFDAYS	CHAR(4 BYTE)

ENROLLMENT	
P * OFFERNO	NUMBER(*10)
P * STUDNO	CHAR(2 BYTE)
ENRGRADE	NUMBER(3,2)

STUDENT	
P * STDNO	
* STD FIRSTNAME	
* STD LASTNAME	
* STD CITY	
* STD STATE	
* STD ZIP	
STD MAJOR	
STD CLASS	
STD GPA	

# Query Clause EVALUATION ORDER:-

Row operations before grouping operations.  
Grouping only occurs one time

## Query Formulation Process:-

Aspects to consider before formulating queries:-

- Databases & tables necessary
- combination of ~~tables~~ columns to link b/w the tables.

- aggregation necessary group of rows (or) individual rows.

## Efficiency Considerations:-

- No extra tables
- No unnecessary grouping
- No missing join conditions.

## Set Operations :-

Union :-  $A \cup B = A + B - (A \cap B) \Rightarrow$  Union  
Intersection :-  $A \cap B \Rightarrow e \in A \& e \in B \Rightarrow$  INTERSECT  
Subtraction :-  $A - B = e \in A \& e \notin B \Rightarrow$  MINUS

## MODIFICATION STATEMENTS in SQL :-

Typical Modification statements are :-

- $\rightarrow$  Insert
- $\rightarrow$  Update
- $\rightarrow$  Delete

No typically used has many database use custom data entry forms. & Backend modification are typically code base inserts.

Syntax:

$\rightarrow$  INSERT INTO TABLE table-name VALUES  
( 's601', Num, Date, 's602'), (---) )

$\rightarrow$  UPDATE table-name SET  
col-name-1 = (xy),  
col-name-2 = (zz)

where colname-3 = (yy)  
AND colname-1 = (xx);

~~Update~~ Update is not possible on Referencing columns like Primary Key

$\rightarrow$  DELETE FROM table-name  
where col1-name = (xx)  
AND col2-name = (yy);

Typically rows in a child table should be deleted before associated rows in parent tables.

## Query Formulation Errors:-

### Types of Errors:

Syntax  
occurs in code  
↳ detected before execution

### Redundancy

↳ excessive resource usage  
↳ too many unnecessary tables & columns involved.

### Semantic

↳ ~~Runtime error~~ ~~or~~  
Incorrect results  
due to failed logic

↳ Missing row condition, column  
(or) parentheses.

### Runtime errors

↳ platform based errors.

## Week #4

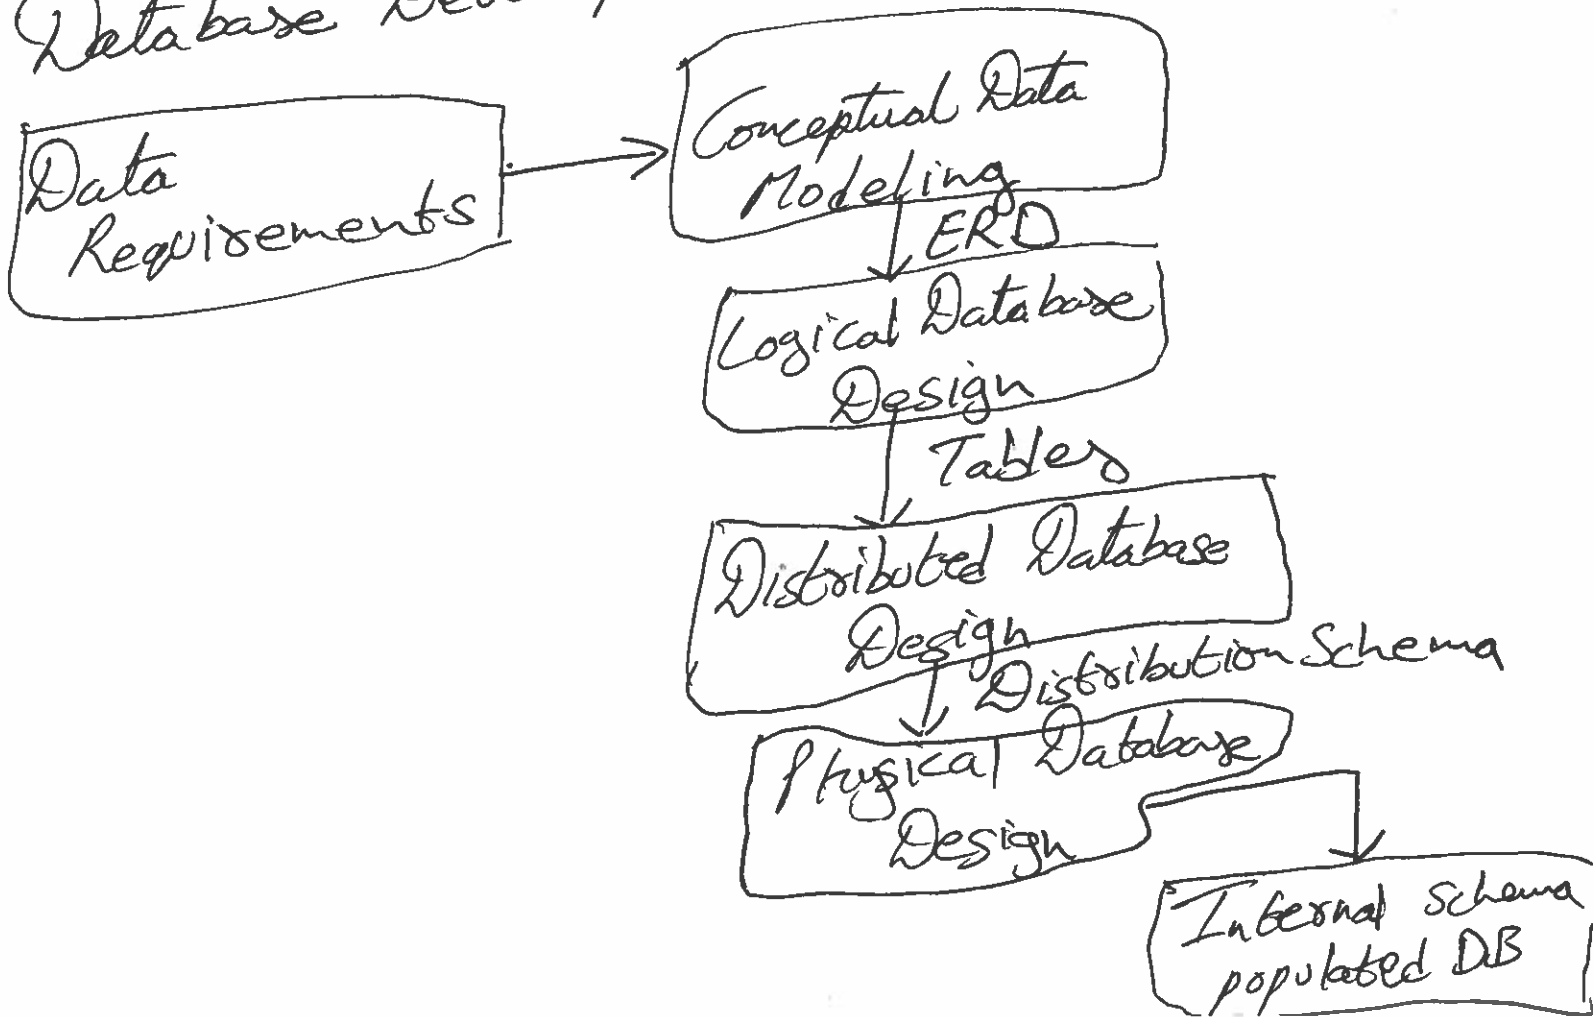

### Notation for Entity Relationship Diagrams

#### Database Development goals :-

Board goals of Database Development:

- A common vocabulary for Data Dictionary
- Define business rules
- Ensure data quality
- Provide efficient implementation.

#### Database Development phases :-

## ERD Notation:-

ERD consists of 3 components:-

- Entity types
- Relationships &
- Attributes

ERD Differs from Relational Database Diagram in the aspects of:

→ Relational Database Diagram Don't use name for relationships instead mark the attributes has Primary Key & Foreign

## Relationship variations:-

Weak entity type:  
borrows parts or entire Primary Key

Identifying relationship:  
Provides a component of a Primary Key for a weak entity type.

Identification dependency:  
A weak entity type & one or more identifying relationships

# Sample ERD :-

- Relation type can be 1 (for one), 0 (for zero) & ∞ (for many).
- Key-type can be PK (primary key) & FK (Foreign key) & ~~UK (Unique key)~~
- Optionally can also include Datatype & int, varchar, string etc... & Constraint type (Unique, not null, check sum & so etc...).

# Week #5

## Developing Business Data Models

### Conceptual data Modeling goals & challenges:-

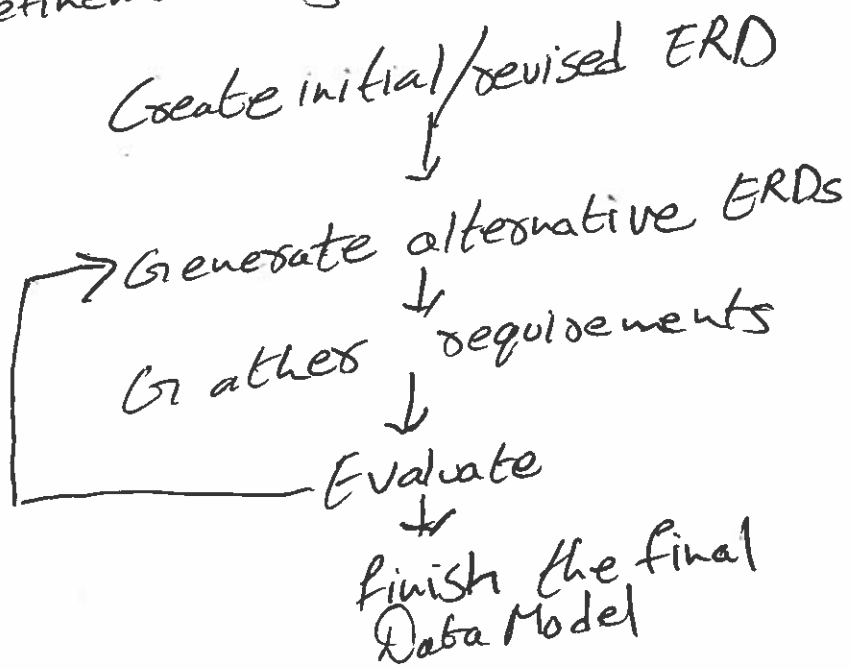

- Analyzing narrative problems
- ~~Process~~ Consistency with narrative
- Identity deficiencies
- Prefer simpler designs
- Identify potential refinements

solution:-

- Identify entity types & attributes
- Determine primary keys based on stability & purpose.
- Identify entity & attribute relationships

### Data Modelling Problems & Completion of an ERD

#### ERD Refinement Cycle:-

# Week#6

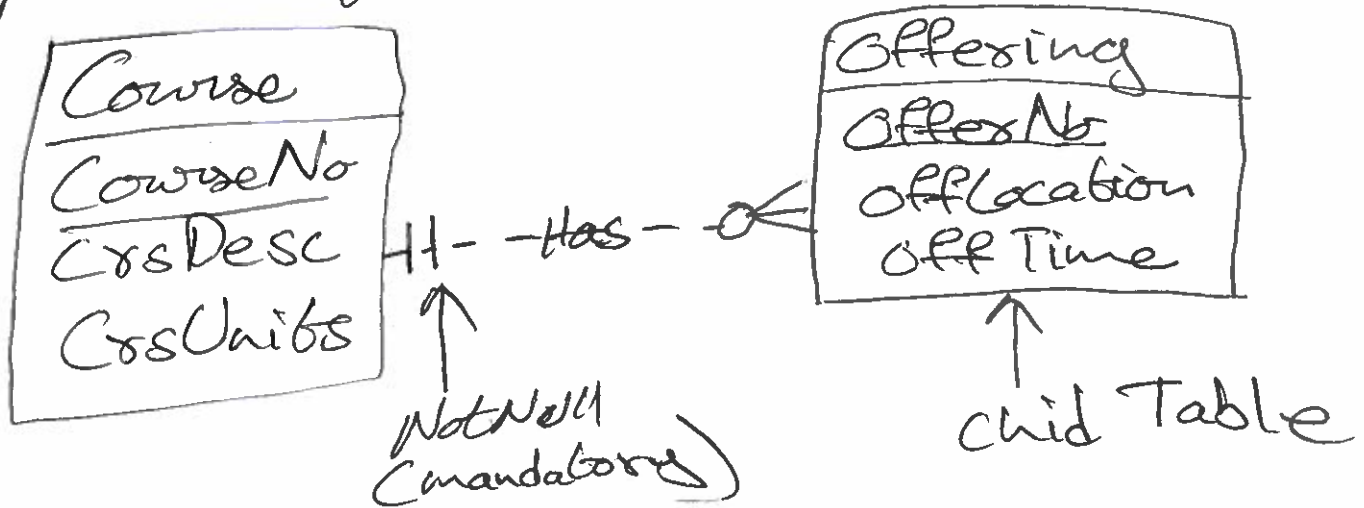

## Schema Conversion

Goals of logical Database Design:-  
Managing Redundancy

logical Database Design +  
Convert • ERD to initial table design  
↓  
Specify • Redundancy Constraints  
↓  
Normalize • Eliminate unwanted redundancies  
↓  
Refine • Uniqueness Constraints  
• other Constraints

Conversion Rule:-  
Entity Type Rule \* Identity Table  
↓  
1-M relationship rule \* FK's in the child table  
↓  
M-N relationship rule \* Associative table plus  
FKs  
\* Combined PK  
↓  
Identifying relationship rule \* Components of PK  
rule

## Application of Basic Rules I: (1 to Many)

```

CREATE TABLE Course(..., PRIMARY KEY
                        (CourseNo))
⇒ CREATE TABLE Offering(..., PRIMARY KEY
                              (OfferNo),
                              FOREIGN KEY (CourseNo) REFERENCES
Course, CONSTRAINT CourseNo NOT NULL)
    
```

## Application of Basic Rules II: (Many to Many)

```

CREATE TABLE Student(..., PRIMARY KEY(StdNo))
CREATE TABLE Offering(..., PRIMARY KEY(OfferNo))
CREATE TABLE Enrollment(..., PRIMARY KEY(StdNo,
OfferNo), FOREIGN KEY (StdNo) REFERENCES Student,
FOREIGN KEY (OfferNo) REFERENCES Offering)
    
```

Strong vs Weak relationship in ERD :-

Weak (Non-Identifying) Relationships

- Entity is existence-independent of other entities.
- PK of child doesn't contain PK component of parent Entity.

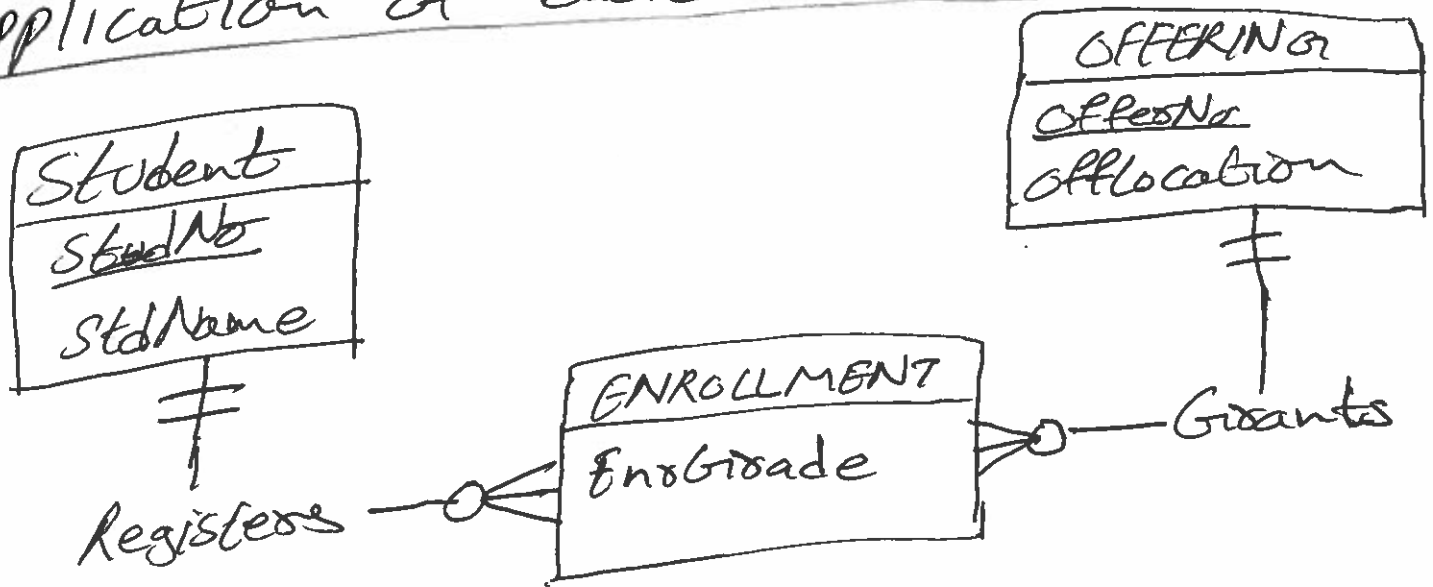

Strong (Identifying) Relationships

- Child entity is existence-dependent on parent.

- PK of Child Entity contains PK component of parent Entity.

- Usually occurs utilizing a composite key for primary-key which means one of this composite key components must be primary key of the parent entity.

# Application of Basic Rules III

Conversion:-

→ Entity type rule is applied 3 times for student, Enrollment, Offering.

→ 1-M relationship rule is applied twice to create FK's student number & offerNo.

→ Because of Weak relationship due to Identification dependency rule both offerNo & "StdNo" are added to the "Enrollment" table.

# University Database ERD:-

# University Database Conversion:-

Entity type rule  $\Rightarrow$

- course
- Student
- Enrollment
- Faculty
- Offering

table

1-M relationship rule

(FK's for child tables from parent tables)

$\Rightarrow$

- Enrollment.StudNo
- Enrollment.OffesNo
- Offering.CourseNo
- Offering.FacNo
- Faculty.FacSupNo

↓  
(added the to self referencing entity in Faculty)

M-N relationship rule

(create new table for the relationship b/w entities & FK's & PK's from both entities into the relationship table)

$\Rightarrow$  No application

Identifying relationship rule

(borrows PK's from depending entities to entities as PK's)

# Week #7

## Normalization Concepts & Practice

Modification anomaly is an unexpected side effect from a row operation. Typically  
Modification anomalies typically occur due to poor Table Design, where an operation for a set of related Tuples can also affect the ~~oper~~ unrelated set of Tuples (example might be a single table Design instead for ~~far~~ university databases.) & ~~for~~ Transaction processing is more sensitive to modification anomalies than B.I processing.

Pros vs Cons :-

Single Tabular Data

→ easy to query due to  
No join operations &  
reduced computational power.

→ less security & Data validity in case of Modification anomalies.

multiple Tabled Data

→ join operation required hence more problem with querying & computing.

→ More security & Data validity in case of Modification anomalies.

## Functional dependencies:-

• Functional dependency is a value neutral constraint similar to primary key & FK's constraints. It involves a comparison of columns.

• Specification of functional dependencies solves the normalization process.

• FD is a constraint about two or more columns of a table.

$\Rightarrow X \text{ determines } Y \Rightarrow X \rightarrow Y \Rightarrow$  for each  $X$  value, there is at most one  $Y$  value.

$\text{Ex: } \rightarrow \text{stdNo} \rightarrow \text{stdCity}$  if each stdNo value

has at most one stdCity value.

similar to uniqueness constraint.

\* Columns with FD should be placed

in the same table.

## Normalization:-

Normalization is the process of removing unwanted redundancy in a table design using Functional dependencies (FD's).

# Normalization process:-

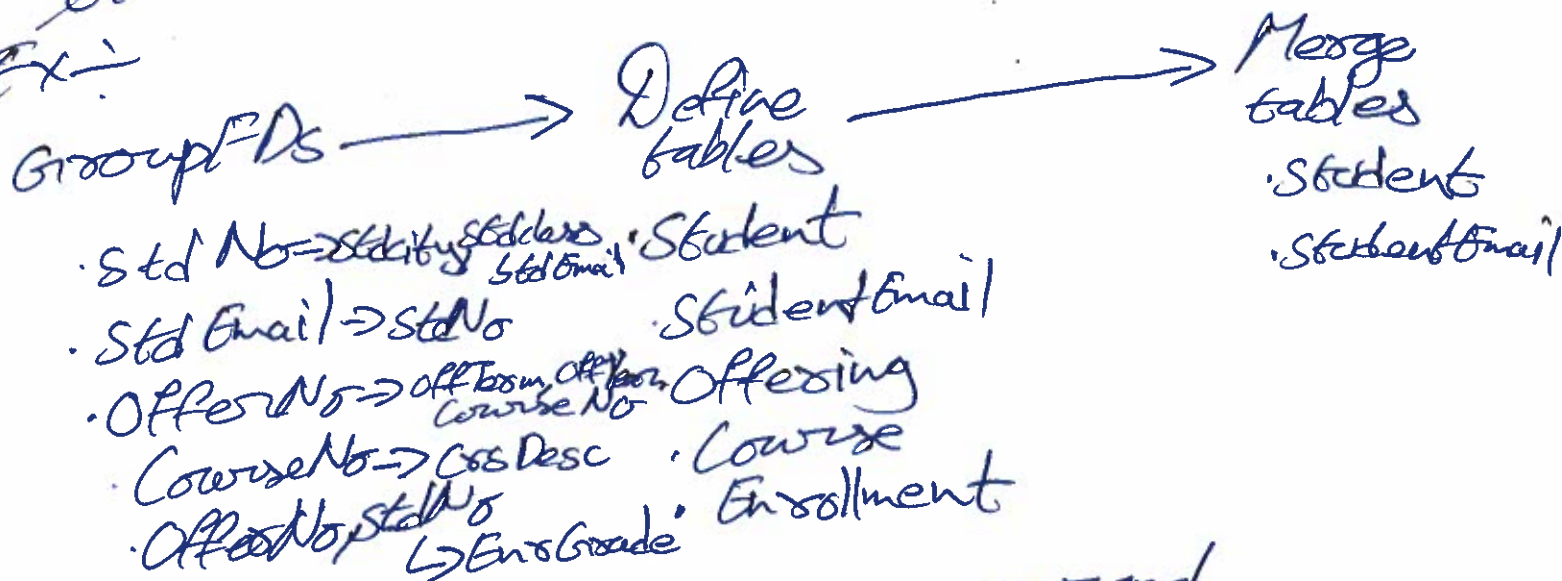

## BOYCE-CODD Normal Form (BCNF) :- Simple Definition of FD's

check if Determinant is unique or not  
↓  
Apply BCNF

Ex:-

Gr
